Abstract

adf

Realtime Sonification of Motion Capture Data

Main intro goes here (why what how?)

Single dollars (\$) are required for inline mathematics e.g. $f(x) = e^{\pi/x}$

Double dollars make self-standing equations:

$$\Theta(x) = \begin{cases} 0 & \text{if } x < 0 \\ 1 & \text{else} \end{cases}$$

For a quick reference, the following citation commands can be used: - Zamm et al. ([2019](#)) -> “Author et al. (2001)” - (Walker et al., [2007](#)) -> “(Author et al., 2001)” - (Umek et al., [2017](#); Vinken et al., [2013](#)) -> “(Author1 et al., 2001; Author2 et al., 2002)”

Literature review (background/etc)

Interpersonal coordination describes situations where two or more individuals strive to match or complement each other's actions, and it is rooted in both the perception and anticipation of motor actions between those individuals (Gerd Schmitz & Alfred O. Effenberg, 2017). While perception, anticipation and action have traditionally been viewed as separate phenomena, current theories state that they are all intrinsically connected. A large part of embodiment research builds on the key hypothesis that merely observing an action triggers internal models of movement that actively engage the motor system (Gerd Schmitz & Alfred O. Effenberg, 2017). As a result, the motor system appears to not only assist with the planning and controlling of one's own actions, but also serves the secondary function of perceiving and anticipating other people's actions (Gerd Schmitz & Alfred O. Effenberg, 2017). This dual-purpose function of the motor system helps with achieving interpersonal coordination and can also result in spontaneous coordination, where the actions of others may unwittingly affect one's own actions, even after being instructed to ignore them (Demos et al., 2012).

Sonification is defined as the use of nonspeech audio to convey information. More specifically, sonification is the transformation of data relations into perceived relations in an acoustic signal for the purposes of facilitating communication or interpretation (Kramer et al., 1999). While concepts around sonification and audification were not formalized until around the year 1992 when the first International Conference on Auditory Display (ICAD) was held (Dubus & Bresin, 2011), practical examples of sonification can be found throughout history. Water clocks in ancient Greece and medieval China were sometimes constructed to produce sounds and thereby provide auditory information about the passage of time (Dubus & Bresin, 2011). The stethoscope, which is used for listening to sounds made by the heart and lungs as well as other internal sounds of the body, was invented in 1816 by French physician and amateur musician Rene Laënnec (Roguin, 2006). The Geiger counter developed in 1928 provides perhaps the most characteristic example of sonification through its function of sonifying levels of radiation. The device detects ionizing radiation and translates it into audible clicks, where a faster tempo signifies a higher level of radiation. Dubus and Bresin (2011) describe the value of the Geiger counter as "transposing a physical quantity which is essentially non-visual and pictured in everyone's imagination as very important because life-threatening, to the auditory modality through clicks with a varying pulse".

....

RQ: To what extent does real-time sonification of object movement effect joint action synchronization between subjects?

H_0: Real-time sonification of object movement has no effect on joint action synchronization between subjects.

H_1: Real-time sonification of object movement effects joint action synchronization between subjects.

Methods

Describe subject demographics etc.

Hardware and Software

Experimental Design

Analysis
